...a modularity-enabled MPI library.

#### Heterogeneous Jobs using inter-module MPI communication

ParaStation MPI provides support for inter-module communication in federated high-speed networks. Therefore, so-called gateway (GW) daemons bridge the MPI traffic between the modules. This mechanism is transparent to the MPI application, i.e., the MPI ranks see a common MPI\_COMM\_WORLD across all modules within the job. However, the user has to account for these additional GW resources during the job submission. An example SLURM Batch script illustrating the submission of heterogeneous pack jobs including the allocation of GW resources can be found here.

#### **Application-dependent Tuning**

The GW protocol supports the fragmentation of larger messages into smaller chunks of a given length, i.e., the Maximum Transfer Unit (MTU). This way, the GW daemon may benefit from pipelining effect resulting in an overlapping of the message transfer from the source to the GW daemon and from the GW daemon to the destination. The chunk size may be influenced by setting the following environment variable:

```
PSP_GW_MTU=<chunk size in byte>
```

The optimal chunk size is highly dependent on the communication pattern and therefore has to be chosen for each application individually.

## **Reporting of Statistical Information**

The recently installed **ParaStation MPI version 5.4.7-1** offers the possibility to collect statistical information and to print a respective report on the number of messages and the distribution over their length at the end of an MPI run. (The so-called psmpi **histogram** feature.) This new feature is currently enabled on DEEP-EST for the psmpi installation in the Devel-2019a stage:

```
> module use $OTHERSTAGES
> module load Stages/Devel-2019a
> module load GCC/8.3.0
> module load ParaStationMPI/5.4.7-1
```

For activating this feature for an MPI run, the PSP\_HISTOGRAM=1 environment variable has to be set:

```
> PSP_HISTOGRAM=1 srun --gw_num=1 -A deep --partition=dp-cn -N2 -n2 ./IMB-MPI1 Bcast -npmin 4 : --partition=dp-dam-ext -N2
srun: psgw: requesting 1 gateway nodes
srun: job 101384 gueued and waiting for resources
srun: job 101384 has been allocated resources

8388608 0
16777216 0
33554432
67108864 0
```

As one can see, the messages being exchanged between all processes of the run are sorted into bins according to their message lengths. The number of bins as well as their limits can be adjusted by the following environment variables:

- PSP\_HISTOGRAM\_MIN (default: 64 bytes) Set the lower limit regarding the message size for controlling the number of bins of the histogram.
- PSP\_HISTOGRAM\_MAX (default: 64 MByte) Set the upper limit regarding the message size for controlling the number of bins of the histogram.
- PSP\_HISTOGRAM\_SHIFT (default: 1 bit position) Set the bit shift regarding the step width for controlling the number of bins of the histogram.

## Example:

```
bin freq
64 16942
256 0
1024 8
4096 0
```

In this example, 16942 messages were smaller than or equal to 64 Byte of MPI payload, while 8 messages were greater than 256 Byte but smaller than or equal to 1024 Byte.

Please note at this point that all messages larger than PSP\_HISTOGRAM\_MAX are as well counted and always fall into the last bin. Therefore, in this example, no message of the whole run was larger than 1024 Byte, because the last bin, labeled with 4096 but collecting all messages larger than 1024, is empty.

#### **Filtering by Connection Type**

An addition that could make this feature quite useful for statistical analysis in the DEEP-EST project is the fact that the message counters can be filtered by connection types by setting the PSP\_HISTOGRAM\_CONTYPE variable. For example, in the following run, only messages that cross the Gateway are recorded:

Connection types for PSP\_HISTOGRAM\_CONTYPEthat might be relevant for DEEP-EST are:

- gw for messages routed via a Gateway
- openib for InfiniBand communication via the pscom4openib plugin
- velo for Extoll communication via the pscom4velo plugin
- shm for node-local communication via shared-memory.

### A note on performance impacts

The collection of statistical data generates a small overhead, which may be reflected in the message latencies in particular. It is therefore recommended to set PSP\_HISTOGRAM=0 for performance benchmarking — or even better to use another psmpi version and/or installation where this feature is already disabled at compile time.

## **Modularity-aware Collectives**

### **Feature Description**

In the context of DEEP-EST and MSA, ParaStation MPI has been extended by modularity awareness also for collective MPI operations. In doing so, an MSA-aware collective operation is conducted in a hierarchical manner where the intra- and inter- module phases are strictly separated:

- i. First do all module-internal gathering and/or reduction operations if required.
- ii. Then perform the inter-module operation with only one process per module being involved.

iii. Finally, distribute the data within each module in a strictly module-local manner.

This approach is here exemplarily shown in the following figure for a Broadcast operation with nine processes and three modules:

Besides Broadcast, the following collective operations are currently provided with this awareness:

- MPI\_Bcast/MPI\_Ibcast
- MPI\_Reduce/MPI\_Ireduce
- MPI\_Allreduce/MPI\_Iallreduce
- MPI\_Scan/MPI\_Iscan
- MPI\_Barrier

### **Feature Usage**

For activating/controlling this feature, the following environment variables must/can be used:

```
- PSP_MSA_AWARENESS=1 # Generally activate the consideration of modular topologies (NOT enabled by default)
- PSP_MSA_AWARE_COLLOPS=0|1|2 # Select the feature level:
0: Disable MSA awareness for collective MPI operations
1: Enable MSA awareness for collective MPI operations (default if PSP_MSA_AWARENESS=1 is set)
2: Apply MSA awareness recursively in multi-level topologies (set PSP_SMP_AWARENESS=1 in addition)
```

In the recursive application of MSA awareness (PSP\_MSA\_AWARE\_COLLOPS=2), a distinction is first made between inter- and intra-module communication and then, in a second step, likewise between inter- and intra-node communication within the modules if PSP\_SMP\_AWARENESS=1 is set in addition. (Please note that a meaningful usage of PSP\_MSA\_AWARE\_COLLOPS=2 requires psmpi-5.4.5 or higher.)

#### Usage with older versions

For psmpi versions before 5.4.6, the Module IDs (PSP\_MSA\_MODULE\_ID) were not set automatically! This means that the user had to set and pass this variable explicitly, for example, via a bash script:

```
#!/bin/bash
# Script (script0.sh) for Module 0: (e.g. Cluster)
APP="./IMB-MPI1 Bcast"
export PSP_MSA_AWARENESS=1
export PSP_MSA_MODULE_ID=0 # <- set an arbitrary ID for this module!
./${APP}</pre>
```

```
#!/bin/bash
# Script (script1.sh) for Module 1: (e.g. ESB)
APP="./IMB-MPI1 Bcast"
export PSP_MSA_AWARENESS=1
export PSP_MSA_MODULE_ID=1 # <- set a different ID for this module!
./${APP}</pre>
```

```
> srun ./script0 : ./script1
```

Since psmpi-5.4.6, the Module ID is set automatically, which means that you can omit all the script stuff above.

However, you can still use PSP\_MSA\_MODULE\_ID and the script approach if you want to set the Module IDs *explicitly*, e.g. for debugging and/or emulating reasons.

## **CUDA Support by ParaStation MPI**

#### What is CUDA awareness for MPI?

In brief, CUDA awareness in an MPI library means that a mixed CUDA + MPI application is allowed to pass pointers to CUDA buffers (these are memory regions located on the GPU, the so-called Device memory) directly to MPI functions such as MPI\_Send() or MPI\_Recv(). A non CUDA-aware MPI library would fail in such a case because the CUDA-memory cannot be accessed directly, e.g., via load/store or memcpy() but has to be transferred in advance to the host memory via special routines such as cudaMemcpy(). As opposed to this, a CUDA-aware MPI library recognizes that a pointer is associated with a buffer within the device memory and can then copy this buffer prior to the communication into a temporarily host buffer — what is called

staging of this buffer. Additionally, a CUDA-aware MPI library may also apply some kind of optimizations, e.g., by means of exploiting so-called *GPUDirect* capabilities that allow for direct RDMA transfers from and to the device memory.

#### Some external Resources

- ?Getting started with CUDA (by NVIDIA)
- ?NVIDIA GPUDirect Overview (by NVIDIA)
- ?Introduction to CUDA-Aware MPI (by NVIDIA)

#### Current status on the DEEP system

Currently (effective October 2019), ParaStation MPI supports CUDA-awareness for Extoll just from the semantic-related point of view: The usage of Device pointers as arguments for send and receive buffers when calling MPI functions is supported but by an explicit *Staging* when Extoll is used. This is because the Extoll runtime up to now does not support GPUDirect, but EXTOLL is currently working on this in the context of DEEP-EST. As soon as GPUDirect will be supported by Extoll, this will also be integrated and enabled in ParaStation MPI. (BTW: For InfiniBand communication, ParaStation MPI is already GPUDirect enabled.)

#### Usage on the DEEP system

**Warning:** This manual section is currently under development. Therefore, the following usage guidelines may be not flawless and are likely to change in some respects in the near future!

On the DEEP system, the CUDA awareness can be enabled by loading a module that links to a dedicated ParaStation MPI library providing CUDA support:

```
module load GCC
module load ParaStationMPI/5.4.0-1-CUDA
```

Please note that CUDA-awareness might impact the MPI performance on systems parts where CUDA is not used. Therefore, it might be useful (and the other way around necessary) to disable/enable the CUDA-awareness. Furthermore, additional optimisations such as GPUDirect, i.e., direct RMA transfers to/from CUDA device memory, are available with certain pscom plugins depending on the underlying hardware. The following environment variables may be used to influence the CUDA awareness in ParaStation MPI

```
PSP_CUDA=0|1 # disable/enable CUDA awareness
PSP_UCP=1 # support GPUDirect via UCX in InfiniBand networks (e.g., this is currently true for the ESB nodes)
```

## **NAM Integration for ParaStation MPI**

## **Documentation**

- Proposal for accessing the NAM via MPI
- API Prototype Implementation
- Usage Example on the DEEP-EST SDV

### **API Prototype Implementation**

For evaluating the proposed semantics and API extensions, we have already developed a shared-memory-based prototype implementation where the persistent NAM is (more or less) ?emulated? by persistent shared-memory (with deep\_mem\_kind=deep\_mem\_persistent).

## Advice to users

Please note that this prototype is not intended to actually emulate the NAM but shall rather offer a possibility for the later users and programmers to evaluate the proposed semantics from the MPI application?s point of view. Therefore, the focus here is not put on the question of how remote memory is managed at its location (currently by MPI processes running local to the memory later by the NAM manager or the NAM itself), but on the question of how process-foreign memory regions can be exposed locally. That means that (at least currently) for accessing a persistent RMA window, it has to be made sure that there is at least one MPI process running locally to each of the window?s memory regions.

#### **Extensions to MPI**

The API proposal strives to stick to the current MPI standard as close as possible and to avoid the addition of new API functions and other symbols. However, in order to make the usage of the prototype a little bit more convenient for the user, we have added at least a small set of new symbols (denoted with MPIX) that may be used by the applications.

## Code Example for a ?Hello World? workflow

The following two C codes should demonstrate how it shall become possible to pass intermediate data between two subsequent steps of a workflow (Step 1: hello / Step 2: world) via the persistent memory of the NAM (currently emulated by persistent shared-memory):

```
/** hello.c **/
    /* Create persistent MPI RMA window: */
      MPI_Info_create(&win_info);
      MPI_Info_set(win_info, "deep_mem_kind", "deep_mem_persistent");
      MPI_Win_allocate(sizeof(char) * HELLO_STR_LEN, sizeof(char), win_info, MPI_COMM_WORLD,
                                         &win_base, &win);
       /* Put some content into the local region of the window: */
      if(argc > 1) {
              snprintf(win_base, HELLO_STR_LEN, "Hello World from rank %d! %s", world_rank, argv[1]);
      } else {
              snprintf(win_base, HELLO_STR_LEN, "Hello World from rank %d!", world_rank);
      MPI_Win_fence(0, win);
      /* Retrieve port name of window: */
      MPI_Info_free(&win_info);
      MPI_Win_get_info(win, &win_info);
      MPI_Info_get(win_info, "deep_win_port_name", INFO_VALUE_LEN, info_value, &flag);
      if(flag) {
              strcpy(port_name, info_value);
              if(world_rank == root) printf("(%d) The Window's port name is: %s\n", world_rank, port_name);
      } else {
               if(world_rank == root) printf("(%d) No port name found!\n", world_rank);
```

```
/** world.c **/

    /* Check for port name: (to be passed as a command line argument) */
    if(argc == 1) {
        if(world_rank == root) printf("[%d] No port name found!\n", world_rank);
        goto finalize;
    } else {
            strcpy(port_name, argv[1]);
            if(world_rank == root) printf("[%d] The Window's port name is: %s\n", world_rank, port_name);
    }

    /* Try to connect to the persistent window: */
    MPI_Info_create(&win_info);
```

```
MPI_Info_set(win_info, "deep_win_connect", "true");
MPI_Comm_set_errhandler(MPI_COMM_WORLD, MPI_ERRORS_RETURN);
errcode = MPI_Comm_connect(port_name, win_info, root, MPI_COMM_WORLD, &inter_comm);
printf("[\$d] \ Connection \ to \ persistent \ memory \ region \ established!\\ \\ \ \ \ \ world\_rank);
 /* Retrieve the number of remote regions: (= former number of ranks) */
MPI_Comm_remote_size(inter_comm, &remote_size);
if(world_rank == root) printf("[%d] Number of remote regions: %d\n", world_rank, remote_size);
/* Create window object for accessing the remote regions: */
MPI_Win_create_dynamic(MPI_INFO_NULL, inter_comm, &win);
MPI_Win_get_attr(win, MPI_WIN_CREATE_FLAVOR, &create_flavor, &flag);
assert(*create_flavor == MPIX_WIN_FLAVOR_INTERCOMM);
MPI_Win_fence(0, win);
/* Check the accessibility and the content of the remote regions: */
for(i=0; i<remote_size; i++) {</pre>
        char hello_string[HELLO_STR_LEN];
        MPI_Get(hello_string, HELLO_STR_LEN, MPI_CHAR, i, 0, HELLO_STR_LEN, MPI_CHAR, win);
        MPI_Win_fence(0, win);
        printf("[%d] Get from %d: %s\n", world_rank, i, hello_string);
}
```

#### Usage Example on the DEEP-ER SDV

On the DEEP-ER SDV, there is already a special version of ParaStation MPI installed that features all the introduced API extensions. It is accessible via the module system:

```
> module load parastation/5.2.1-1-mt-wp6
```

When allocating a session with N nodes, one can run an MPI session (let?s say with n processes distributed across the N nodes) where each of the processes is contributing its local and persistent memory region to an MPI window:

```
> salloc --partition=sdv --nodes=4 --time=01:00:00
salloc: Granted job allocation 2514
> srun -n4 -N4 ./hello 'Have fun!'
(0) Running on deeper-sdv13
(1) Running on deeper-sdv14
(2) Running on deeper-sdv15
(3) Running on deeper-sdv16
(0) The Window's port name is: shmid:347897856:92010569
(0) Calling finalize...
(1) Calling finalize...
(2) Calling finalize...
(3) Calling finalize...
(0) Calling finalize...
(0) Finalize done!
(1) Finalize done!
(2) Finalize done!
(3) Finalize done!
```

Afterwards, on all the nodes involved (and later on the NAM) one persistent memory region has been created by each of the MPI processes. The ?port name? for accessing the persistent window again is in this example:

```
shmid:347897856:92010569
```

By means of this port name (here to be passes as a command line argument), all the processes of a subsequent MPI session can access the persistent window provided that there is again at least one MPI processes running locally to each of the persistent but distributed regions:

```
> srun -n4 -N4 ./world shmid:347897856:92010569
[0] Running on deeper-sdv13
[1] Running on deeper-sdv14
[2] Running on deeper-sdv15
[3] Running on deeper-sdv16
[0] The Window's port name is: shmid:347897856:92010569
[1] Connection to persistent memory region established!
[3] Connection to persistent memory region established!
[0] Connection to persistent memory region established!
[2] Connection to persistent memory region established!
[0] Number of remote regions: 4
[0] Get from 0: Hello World from rank 0! Have fun!
[1] Get from 0: Hello World from rank 0! Have fun!
[2] Get from 0: Hello World from rank 0! Have fun!
[3] Get from 0: Hello World from rank 0! Have fun!
[0] Get from 1: Hello World from rank 1! Have fun!
[1] Get from 1: Hello World from rank 1! Have fun!

[1] Get from 3: Hello World from rank 3! Have fun!
[2] Get from 3: Hello World from rank 3! Have fun!
[3] Get from 3: Hello World from rank 3! Have fun!
[0] Calling finalize...
[1] Calling finalize...
[2] Calling finalize...
[3] Calling finalize...
[0] Finalize done!
[1] Finalize done!
[2] Finalize done!
[3] Finalize done!
```

## Advice to users

Pleases note that if not all persistent memory regions are covered by the subsequent session, the ?connection establishment? to the remote RMA window fails:

```
> srun -n4 -N2 ./world shmid: 347897856:92010569
[3] Running on deeper-sdv14
[1] Running on deeper-sdv13
[2] Running on deeper-sdv14
[0] Running on deeper-sdv13
[0] The Window's port name is: shmid:347930624:92010569
[0] ERROR: Could not connect to persistent memory region!
application called MPI_Abort(MPI_COMM_WORLD, -1)
?
```

## Cleaning up of persistent memory regions

If the connection to a persistent memory region succeeds, the window and all of its memory regions will eventually be removed by the MPI\_Win\_free call of the subsequent MPI session (here by world.c) at least if not deep\_mem\_persistent is passes again as an Info argument. However, if a connection attempt fails, the persistent memory regions still persist.

For explicitly cleaning up those artefacts, one can use a simple batch script:

```
#!/bin/bash
keys=`ipcs | grep 777 | cut -d' ' -f2`
```

```
for key in $keys ; do
    ipcrm -m $key
done
```

# Advice to administrators

Obviously, a good idea would be the integration of e such an automated cleaning-up procedure as a default into the epilogue scripts for the jobs.
